”

Web developers are younger siblings of musical artists.

Web Audio API

The Web Audio API provides a powerful and versatile system for controlling audio on the Web, allowing developers to choose audio sources, add effects to audio, create audio visualizations, apply spatial effects (such as panning) and much more.

Web audio concepts and usage

The Web Audio API involves handling audio operations inside an **audio context**, and has been designed to allow **modular routing**. Basic audio operations are performed with **audio nodes**, which are linked together to form an **audio routing graph**. Several sources — with different types of channel layout — are supported even within a single context. This modular design provides the flexibility to create complex audio functions with dynamic effects.

Challenges with Web Audio API

- Web audio components are mutable objects
- Memory management is crucial thing
- Sound routing is similar to journey of data across the app

What’s the use case for Web Audio API?

- Simple games
- Web application with simple sound manipulations
  - guitar tuner
  - media players (based on streamed sound)
  - simple sound editors (i.e. for podcasts)
- Sound sources reacting on level of ambient noises
  - checkout kiosks
  - aircraft intercoms
